1. Statistical relative protein quantification: SRM, DDA and DIA experiments

MSstats is an open-source R-based package for statistical relative quantification of peptides and proteins in mass spectrometry-based proteomic experiments. This document describes MSstats, the most recent version of the package, and its use through the command line.

1.1 Applicability

MSstats version 3.0 and above is applicable to multiple types of sample preparation, including label-free workflows, workflows that use stable isotope labeled reference proteins and peptides, and workflows that use fractionation. It is applicable to targeted Selected Reaction Monitoring (SRM), Data-Dependent Acquisition (DDA or shotgun), and Data-Independent Acquisition (DIA or SWATH-MS). It is applicable to experiments that make arbitrary complex comparisons of experimental conditions or times.

MSstats is not applicable to experiments that compare multiple metabolically labeled endogenous samples within a same run, such as experiments with iTRAQ labeling or TMT labeling. These experiments are supported by MSstatsTMT, which is a sibling package. Please check MSstatsTMT in Bioconductor.

1.2 Statistical functionalities

MSstats version 3.0 and above performs three analysis steps. The first step, data processing, visualization, and run-level summarization, transforms, normalizes and summarizes the intensities of the peaks per MS run and per protein, and generates workflow-specific and customizable numeric summaries for data visualization and quality control.

The second step, statistical modeling and inference, automatically detects the experimental design (e.g. group comparison, paired design or time course, presence of labeled reference peptides or proteins) from the data. It then reflects the experimental design and the type of spectral acquisition strategy, and fits an appropriate linear mixed model by means of 1m and 1mer functionalities in R. The model is used to detect differentially abundant proteins or peptides, or to summarize the protein or peptide abundance in a single biological replicate or condition (that can be used, e.g. as input to clustering or classification).

The third step, *statistical experimental design*, views the dataset being analyzed as a pilot study of a future experiment, utilizes the variance components of the current dataset, and calculates the minimal number of replicates necessary in the future experiment to achieve a pre-specified statistical power.

1.3 Interoperability with existing computational tools

MSstats takes as input data in a tabular .csv format, which can be generated by any spectral processing tool such as Skyline (MacLean et al. 2010), MaxQuant (Cox and Mann 2008), Progenesis QI (Nonlinear dynamics/Waters), Proteome Discoverer (Thermo Scientific), MultiQuant(Applied Biosystems), OpenMS (Sturm et al. 2008), SuperHirn (Mueller et al. 2007), OpenSWATH (Röst et al. 2014), Spectronaut (Biognosys), or DIA-Umpire (Tsou et al. 2015). The functions to convert the required format from several processing tools are available from MSstats v3.6. Details are in the section below.

For statistics experts, MSstats 3.0 and above satisfies the interoperability requirements of Bioconductor. The command line-based workflow is partitioned into a series of independent steps, that facilitate the development and testing of alternative statistical approaches. It complies with the maintenance and documentation requirements of Bioconductor.

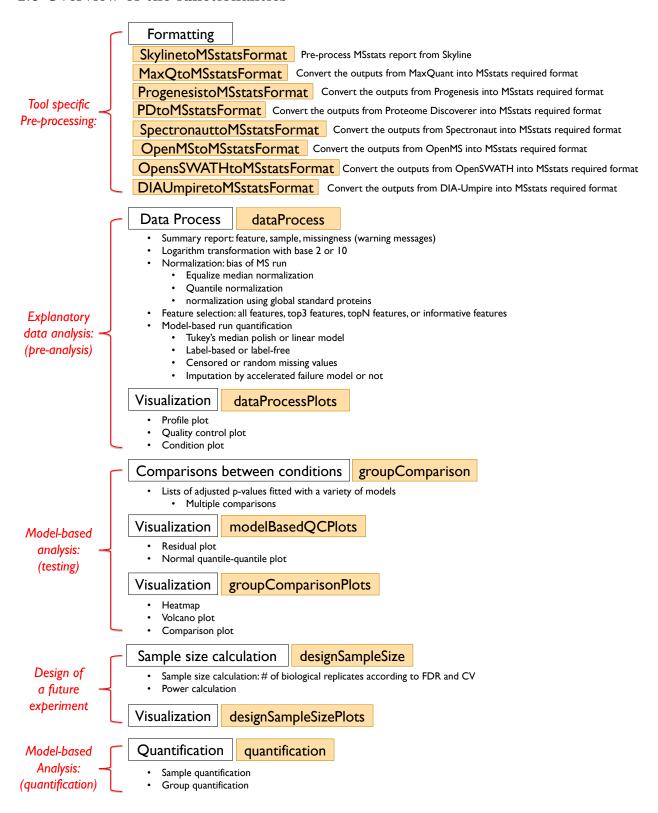

MSstats 3.0 and above is available as an external tool within Skyline. The external tool support within Skyline manages MSstats installation, point-and-click execution, parameter collection in Windows forms and

output display. Skyline manages the annotations of the experimental design, and the processing of raw data. It outputs a custom report, that is fed as a single stream input into MSstats. This design buffers proteomics users from the details of the R implementation, while enabling rigorous statistical modeling. Also, MSstat can be combined with an OpenMS preprocessing pipeline (e.g. in KNIME). The OpenMS experimental design is used to present the data in an MSstats-conformant way for the analysis. Details are available in OpenMS tutorial.

1.4 Availability

MSstats is available under the Artistic-2.0 license at msstats.org. MSstats as an external tool for Skyline is available at http://proteome.gs.washington.edu/software/Skyline/tools.html. MSstats is now also available in Bioconductor. The most recent version of the package is available at msstats.org or MSstats GitHub. We suggest to use that if possible. The versioning of the main package is updated several times a year, to synchronise with the Bioconductor release.

1.5 Overview of the functionalities

1.6 Troubleshooting

To help troubleshoot potential problems with installation or functionalities of MSstats, a progress report is generated in a separate log file, msstats.log. The file includes information on the R session (R version, loaded software libraries), options selected by the user, checks of successful completion of intermediate analysis steps, and warning messages. If the analysis produces an error, the file contains suggestions for possible reasons for the errors. If a file with this name already exists in working directory, a suffix with a number will be appended to the file name. In this way a record of all the analyses is kept. Please see the file KnownIssues-Skyline-MSstatsV3.6.pdf on the "Installation" section of "MSstats" page in msstats.org for a list of known issues and possible solutions for installation problem of MSstats external tool in Skyline

2. Allowable data formats

2.1 SRM with stable isotope labeled reference peptides

2.1.1 10-column format

MSstats performs statistical analysis steps, that follow peak identification and quantitation. Therefore, input to MSstats is the output of other software tools (such as Skyline or MultiQuant) that read raw spectral files and identify and quantify spectral peaks. The preferred structure of data for use in MSstats is a .csv file in a "long" format with 10 columns representing the following variables: ProteinName, PeptideSequence, PrecursorCharge, FragmentIon, ProductCharge, IsotopeLabelType, Condition, BioReplicate, Run, Intensity. The variable names are fixed, but are case-insensitive.

- (a) ProteinName: This column needs information about Protein id. Statistical analysis will be done separately for each unique label in this column. For peptide-level modeling and analysis, use peptide id in this column.
- (b)-(e) PeptideSequence, PrecursorCharge, FragmentIon, ProductCharge: The combination of these 4 columns defines a *feature* of a protein (in SRM experiments, it is a transition that is identified and quantified across runs). If the information for one or several of these columns is not available, please do not discard these columns but use a single fixed value across the entire dataset. For example, if the original raw data does not contain the information of ProductCharge, assign the value 0 to the entries in the column ProductCharge for the entire dataset. If the peptide sequences should be distinguished based on post-translational modifications, this column can be renamed to PeptideModifiedSequence. For example, this allows us to use the PeptideModifiedSequence column from the Skyline report.
 - (f) IsotopeLabelType: This column indicates whether this measurement is based on the endogenous peptides (use "L") or labeled reference peptides (use "H").
 - (g) Condition: For group comparison experiments, this column indicates groups of interest (such as "Disease" or "Control"). For time-course experiments, this column indicates time points (such as "T1", "T2", etc). If the experimental design contains both distinct groups of subjects and multiple time points per subject, this column should indicate a combination of these values (such as "Disease_T1", "Disease_T2", "Control_T1", "Control_T2", etc.).
 - (h) BioReplicate: This column should contain a unique identifier for each biological replicate in the experiment. For example, in a clinical proteomic investigation this should be a unique patient id. Patients from distinct groups should have distinct ids. MSstats does not require the presence of technical replicates in the experiment. If the technical replicates are present, all samples or runs from a same biological replicate should have a same id. MSstats automatically detects the presence of technical replicates and accounts for them in the model-based analysis.

- (i) Run: This column contains the identifier of a mass spectrometry run. Each mass spectrometry run should have a unique identifier, regardless of the origin of the biological sample. In SRM experiments, if all the transitions of a biological or a technical replicate are split into multiple "methods" due to the technical limitations, each method should have a separate identifier. When processed by Skyline, distinct values of runs correspond to distinct input file names. It is possible to use the actual input file names as values in the column Run.
- (j) Intensity: This column should contain the quantified signal of a feature in a run without any transformation (in particular, no logarithm transform). The signals can be quantified as the peak height or the peak of area under curve. Any other quantitative representation of abundance can also be used.

An example of an acceptable input dataset is shown below. This example dataset is from an SRM experiment with stable isotope labeled reference peptides. The dataset is stored in a .csv file in a "long" format. Each row corresponds to a single intensity. More details on assigning the values of Condition, BioReplicate and Run, depending on the structure of the experimental design, are given below.

0	A	В	C	D	E	F	G	Н		j
1	ProteinName	PeptideSequence	PrecursorCharge	FragmentIon	ProductCharge	IsotopeLabelType	Condition	BioReplicate	Run	Intensity
2	ACEA	EILGHEIFFDWELP	3	y3	0	Н	1	ReplA	1	66472.3847
3	ACEA	EILGHEIFFDWELP	3	у3	0	L	1	ReplA	1	5764.16228
4	ACEA	EILGHEIFFDWELP	3	y4	0	H	1	ReplA	1	101005.166

13	ACEA	TDSEAATLISSTID'	2	y8	0	L	1	ReplA	1	243.658527

2.1.2 Assigning the values of Condition, BioReplicate and Run

The values of Condition, BioReplicate, Run depend on the design of the specific experiment.

1) Group comparison In a group comparison design, the conditions (e.g., disease states) are profiled across non-overlapping sets of biological replicates (i.e., subjects). In this example there are 2 conditions, Disease and Control (in general the number of conditions can vary). There are 3 subjects (i.e., biological replicates) per condition (in general an equal number of replicates per condition is not required). Each subject has 2 technical replicate runs (in general technical replicates are not required, and their number per sample may vary). Overall, in this example there are $2 \times 3 \times 2 = 12$ mass spectrometry runs.

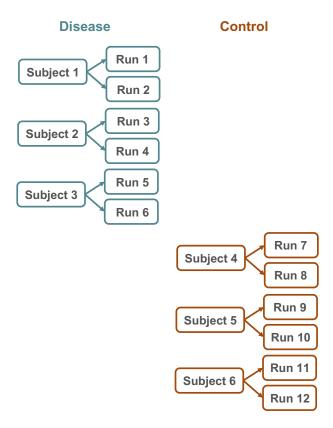

Table below shows the values of the columns Condition, BioReplicate and Run for this situation. It is important to note two things. First, the order of subjects and conditions in the experiment should be randomized, and run id does not need to represent the order of spectral acquisition. Second, the values of the columns are repeated for every quantified transition. For example, if in each run the experiment quantifies 50 endogenous transitions and 50 labeled reference counterparts, then the input file has $12 \times 50 \times 2 = 1200$ lines. When a feature intensity is missing in a run, the data structure should contain a separate row for each missing value. The rows should include all the information (from ProteinName to Run), and indicate missing intensities with NA.

Condition	BioReplicate	Run
Disease	Subject1	1
Disease	Subject1	2
Disease	Subject2	3
Disease	Subject2	4
Disease	Subject3	5
Disease	Subject3	6
Control	Subject4	7
Control	Subject4	8
Control	Subject5	9
Control	Subject5	10
Control	Subject6	11
Control	Subject6	12

2) Time course The important feature of a time course experimental design is that a same subject (i.e., biological replicate) is repetitively measured across multiple time points. In this example there are 2 time points, Time1 and Time2 (in general the number of times can vary). There are 4 subjects (i.e., biological replicates) measured across times (in general an equal number of times per replicate is not

required). There are no technical replicates (in general the number of technical replicates per sample may vary). Overall, in this example there are $2 \times 4 \times 1 = 8$ mass spectrometry runs.

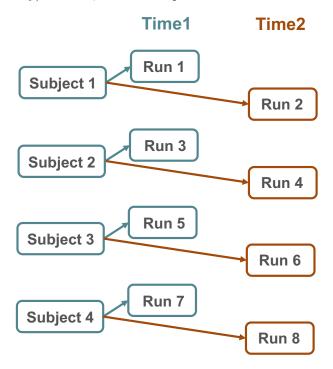

Table below shows the values of the columns Condition, BioReplicate and Run for this situation. Comments on the order of the runs, on the number of lines in the input data structure, and on the handling of missing peak intensities are as in the group comparison design.

Condition	BioReplicate	Run
Time1	Subject1	1
Time2	Subject1	2
Time1	Subject2	3
Time2	Subject2	4
Time1	Subject3	5
Time2	Subject3	6
Time1	Subject4	7
Time2	Subject4	8

3) Paired design Another frequently used experimental design is a paired design, where measurements from multiple conditions (such as healthy biopsy and disease biopsy) are taken from a same subject. The statistical model for this experimental design is the same as in the time course experiment, however the values in the columns of the input data may have a different appearence. In this example there are 2 subjects, PatientA and PatientB (in general the number of patients can vary). There are two conditions per subject, BiopsyHealthy and BiopsyTumor (in general the number of conditions per subject can exceed two). In this example there are 3 technical replicates of each type (in this example, the technical replicates are biopsies; in general these can also be replicate sample preparations or replicate mass spectrometry runs). Overall, in this example there are $2 \times 2 \times 3 = 12$ mass spectrometry runs.

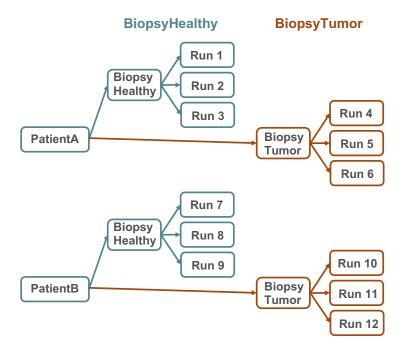

Table below shows the values of the columns Condition, BioReplicate and Run for this situation. Comments on the order of the runs, on the number of lines in the input data structure, and on the handling of missing peak intensities are as in the group comparison design.

Condition	BioReplicate	Run
BiopsyHealthy	PatientA	1
BiopsyHealthy	PatientA	2
BiopsyHealthy	PatientA	3
BiopsyTumor	PatientA	4
BiopsyTumor	PatientA	5
BiopsyTumor	PatientA	6
BiopsyHealthy	PatientB	7
BiopsyHealthy	PatientB	8
BiopsyHealthy	PatientB	9
BiopsyTumor	PatientB	10
BiopsyTumor	PatientB	11
BiopsyTumor	PatientB	12

2.2 Label-free DDA

For label-free DDA experiments the required input is the 10-column format, the same as described in section 2.1 for SRM experiments. In DDA experiments spectral features are defined as peptide ions, which are identified and quantified across runs. Since for label-free DDA experiments some of the columns PeptideSequence, PrecursorCharge, FragmentIon, and ProductCharge are not relevant, these columns will have a constant fixed value (such as NA) across the entire dataset. Furthermore, the column IsotopeLabelType will be set to "L" for the entire dataset.

ProteinName	PeptideSequence	PrecursorCharge	Fragmention	ProductCharge	IsotopeLabelType	Condition	BioReplicate	Run	Intensity
bovine	S.PVDIDTK	5	NA	NA	L	C1	1	1	2636791.5
bovine	S.PVDIDTK	5	NA	NA	L	C1	1	2	1992418.5
bovine	S.PVDIDTK	5	NA	NA	L	C1	1	3	1982146.38
bovine	S.PVDIDTK	5	NA	NA	L	C2	1	4	5019594
bovine	S.PVDIDTK	5	NA	NA	L	C2	1	5	4560467.5
bovine	S.PVDIDTK	5	NA	NA	L	C2	1	6	3627848.75
bovine	S.PVDIDTK	5	NA	NA	L	C5	1	13	145511.83
bovine	S.PVDIDTK	5	NA	NA	L	C5	1	14	291829.69
bovine	S.PVDIDTK	5	NA	NA	L	C6	1	16	786667.38
bovine	S.PVDIDTK	5	NA	NA	L	C6	1	17	705295.31
bovine	S.PVDIDTK	5	NA	NA	L	C6	1	18	453448.78
bovine	S.PVDIDTK	5	NA	NA	L	C3	1	7	NA

2.2 Label-free DIA

For label-free DIA experiments, the required input is the 10-column format, the same as described in section 2.1 for SRM experiments. The values of the required columns can be extracted from the output of signal processing software such as Skyline or OpenSWATH. By default, the combination of the values in the columns PeptideSequence, PrecursorCharge, FragmentIon, ProductCharge uniquely identifies each spectral feature (i.e., a fragment ion identified and quantified across multiple runs). If the signal processing software does not provide the information on some of these columns but provides a unique feature identifier, it is possible to use this unique identifier instead of one of these columns. Furthermore, the column IsotopeLabelType is set to "L" for the entire dataset.

An example dataset is shown below. In this example, feature id generated by OpenSWATH is used instead of ProductCharge to uniquely characterize each feature.

ProteinName	PeptideSequence	PrecursorCharge	Fragmention	ProductCharge	IsotopeLabelType	Condition	BioReplicate	Run	Intensity
350748	TPPAAVLLK	2	y7	109401	L	2	1	3	257486
350748	TPPAAVLLK	2	y7	109401	L	2	2	4	141159
350748	TPPAAVLLK	2	y7	109401	L	1	1	1	452908
350748	TPPAAVLLK	2	y7	109401	L	1	2	2	348222

515084	MVNEAIESLGSIDVLVNNAGITNDK	3	y9	57971	L	1	2	2	10516

3. Prerequisites and setting for MSstats analysis

MSstats is an R-based package. It is assumed that you already have R installed. You can install MSstats from Bioconductor:

```
if (!requireNamespace("BiocManager", quietly = TRUE))
    install.packages("BiocManager")

BiocManager::install("MSstats")
```

Once you have the package installed, load MSstats into an R session and verify that you have the correct version. Note that in order to use MSstats, the package needs to be loaded every time you restart R.

```
library('MSstats', warn.conflicts = F, quietly = T, verbose = F)
?MSstats
sessionInfo()
```

```

```

Finally, set the working directory to where you saved files. Note that you may have a different path on your computer from the example.

```
setwd('/Users/meenachoi/Dropbox/MSstats_GitHub_document/MSstats_v3.18.1')
```

You can check your working directory by:

```
getwd()
```

[1] "/Users/meenachoi/Dropbox/MSstats_GitHub_document/MSstats_v3.18.1"

4. DDA analysis with MSstats

4.1 General workflow for DDA

This section describes a typical workflow for DDA analysis with MSstats. Controlled mixture DDA data will be used for demonstration. This dataset is available as an example data (DDARawData) in MSstats. Also the csv file for the same dataset, RawData.DDA.csv, is available in MSstats material GitHub in the folder named 'example dataset/DDA controlledMixture2009'. It is processed by Superhirn. (original reference link)

4.1.1 Preparing the data for MSstats input

The first step in using the MSstats is to format the data as described in Section 2. DDARawData is already formatted for MSstats input.

```
# Check the first 6 rows in DDARawData
head(DDARawData)

4.1.2 Processing the data

Normalizing and summarizing data with dataProcess After reading the datasets, MSstats performs 1) logarithm transformation of Intensity column, 2) normalization, 3) feature selection, (all features vs subset of features), 4) imputation for censored missing value, which are below the cutoff and undetectable, 5) run-level summarization.

To get started with this function, visit the help section of dataProcess first:

?dataProcess

NOTE At the logarithm transformation step, zero value in Intensity is problematic. When Intensity=0, Inf is the output from logarithm transformed intensities. Also, logarithm transformed intensites, when Intensity < 1, are negative values and it can make overestimated between log fold change. Therefore, logarithm transformed intensities for original intensity between 0 and 1 will be replaced with zero value after normalization.

Default normalization and summarization options dataProcess provides a variety of options in consideration of different experimental protocols. Default values for all options are our suggestion for general cases. However, the default options may not be appropriate for all possible scenarios. It is important to understand their underlying assumption to avoid misuse. Below is the additional explanation for main options.

- logTrans: logarithm transformation with base 2 (default) of Intensity column.
- Normalization:
 - 'equalizeMedians': The default option for normalization is equalizeMedians, where all the intensities in a run are shifted by a constant, to equalize the median of intensities across runs for label-free experiment. This normalization method is appropriate when we can assume that the majority of proteins do not change across runs. Be cautious when using the equalizeMedians option for a label-free DDA dataset with only a small number of proteins. For label based experiment, equalizeMedians equalizes the median of reference intensities across runs and is generally proper even for a dataset with a small number of proteins.
 - 'globalStandards': Instead, if you have a spiked in standard, you may set this to globalStandards and define the standard with nameStandards option.
 - 'quantile': The distribution of all the intensities in each run will become the same across runs for label-free experiment. For label-based experiment, the distribution of all the reference intensities will be become the same across runs and all the endogenous intensities are shifted by a constant corresponding to reference intensities.
 - **FALSE**: No normalization is performed. If you had your own normalization before MSstats, you should use Normalization=FALSE.
 - NOTE : If there are multiple fractionations or injections for one sample, normalization is perform by each fractionation or different m/z range from multiple injections.
- nameStandards: Only for Normalization='globalStandards', global standard peptide or Protein names, which you can assume that they have the same abundance across MS runs, should be assigned in the vector for this option.

• featureSubset :

- 'all': Use all features in the dataset.
- 'top3': Use top 3 features which have highest average of log2(intensity) across runs.
- 'topN': Use top N features which have highest average of log2(intensity) across runs. It needs the input for n_top_feature option (ex. n_top_feature=5 for top 5 features).
- 'highQuality': Detect and flag uninformative features (as Uninformative in the feature_quality column) and outliers (as TRUE in the is_outlier column). These uninformative content may be excluded from run-level summarization by setting the remove_uninformative_feature_outlier option to TRUE.
- summaryMethod : Method for run-level summarization.
 - 'TMP': Default. Tukey's median polish (medpolish function in stats). Robust parameter estimation method with median across rows and columns.
 - 'linear': Linear model (1m function). Average-based summarization.
- MBimpute: whether model-based imputation will be performed or not. Only for summaryMethod='TMP'.
 - TRUE: Default. Censored missing values will be imputed by Accelerated Failure Time model. Censored missing values will be determined by other options, censoredInt and maxQuantileforCensored
 - **FALSE**: No model-based imputation.
- maxQuantileforCensored: Maximum quantile for deciding censored missing value. Default is 0.999. If you don't want to apply the threshold of noise intensity in your data, you can use maxQuantileforCensored=NULL.
- **censoredInt**: The processing tools report missing values differently. This option is for distinguish which value should be considered as missing, and further whether it is censored or at random.
 - 'NA': Default. It assumes that all NAs in Intensity column are censored.
 - '0': It assumes that all values between 0 and 1 in Intensity column are censored. If there are NAs in Intensity with this option, NAs will be considered as random missing.

- **NULL**: It assumes that all missing values are randomly missing.
- cutoffCensored: cutoff value for AFT model. It is only with censoredInt='NA' or censoredInt='0'. If you have censoredInt=NULL, it assumes that there is no censored missing and any imputation will not be performed.
 - 'minFeature': cutoff for AFT model will be the minimum value for each feature across runs.
 - 'minRun': cutoff for AFT model will be the minimum value for each run across features.
 - 'minFeatureNRun': cutoff for AFT model will be the smallest value between minimum value of corresponding feature and minimum value of corresponding run.

A typical label-free DDA dataset may have many missing values and noisy features with outliers. MSstats supports several ways to deal with this. The default option for summarization is TMP (robust parameter estimation method with median across rows and columns) after imputation by AFT (accelerated failure time model, MBimpute=TRUE) based on censored intensity for NA (censoredInt="NA") with a cutoff as the minimum value for a feature (cutoffCensored="minFeature").

This process handles missing values through imputation and reduces the influence of the outliers using the TMP estimation. Note, however, that those runs with no measurements at all will be removed and not be used for any calculation.

```
# default option
DDA2009.proposed <- dataProcess(raw = DDARawData,
                           normalization = 'equalizeMedians',
                           summaryMethod = 'TMP',
                           censoredInt = "NA",
                           cutoffCensored = "minFeature",
                           MBimpute = TRUE,
                           maxQuantileforCensored=0.999)
## ** Log2 intensities under cutoff = 13.456 were considered as censored missing values.
## ** Log2 intensities = NA were considered as censored missing values.
## ** Use all features that the dataset originally has.

DDA2009.TMP\$ProcessedData has the data after normalization and deciding the data-specific threshold for censored missing value. There are several new columns in the datasets. Also dataset is reformated. Intensity column includes original intensities values in the input of dataProcess. ABUNDANCE column contains the log2 transformed and normalized intensities and it will used for run-level summarization. censored column has the decision about censored missing or not, based on censoredInt and maxQuantileforCensored options. ABUNDANCE with TRUE value in censored column will be considered as censored missing and imputed with MBimpute=TRUE option. Censored missing will be distinguished in Profile plot from dataProcessPlots.

DDA2009.TMP\$RunlevelData includes run-level summarized data based on DDA2009.TMP\$ProcessedData. LogIntensities is run-level summarized data and will be used for groupComparison function in next step. It will also used for summarized profile plot (summaryPlot=TRUE for dataProcessPlots function with type='ProfilePlot'). NumMeasuredFeature shows how many features were used for summarization of the corresponding run and protein. MissingPercentage means the percentage of random and censored missing in the corresponding run and protein out of the total number of feature in the corresponding protein. more50missing means whether MissingPercentage is greater than 50% or not. NumImputedFeature show how many features were imputed in the corresponding run and protein.

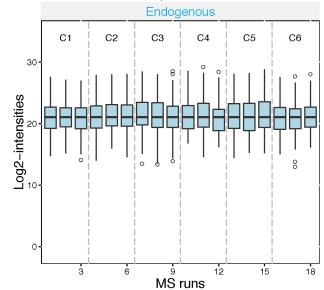

```
# here 'TMP' : It shows which summaryMethod is used for run-level summarization.
head(DDA2009.proposed$SummaryMethod)
```

4.1.3 Visualization of processed data

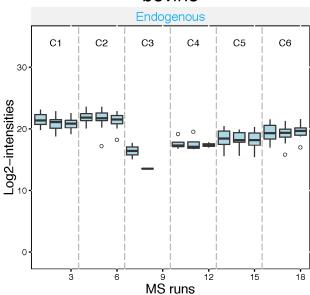

[1] "TMP"

Quality control and normalization effects QC plot visualizes potential systematic biases between mass spectrometry runs. Also it can be used to assess the effects of the normalization step. After constant normalization, the median intensities of reference transitions across all proteins should be equal between runs. After quantile normalization, the distribution of reference intensities across all proteins should be equal between runs. This step generates two types of QC plots: one for all the proteins combined, and the other separately for each protein (produced in a separate pdf file). These plots can be generated for either all proteins at once or each protein individually if we have a large dataset. The example below shows both options.

All proteins

NOTE Don't worry about warning messages as below. It means NA values are not included in the plot, which is a proper way for this case.

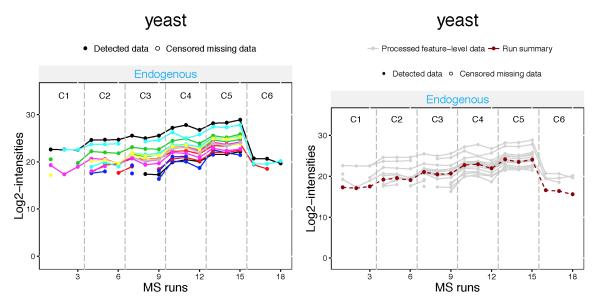

Warning messages:

1: Removed 698 rows containing non-finite values (stat_boxplot).

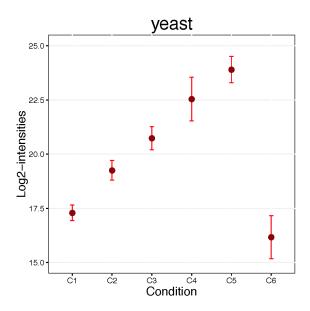

. . .

Profile plot Profile plot helps identify potential sources of variation (both variation of interest and nuisance variation) for each protein. Such plots should be done after the normalization. Profile plots with summarization present the effects of the summarization step by showing all individual measurements of a protein and their summarized intensity. With type="profileplot", two pdfs will be generated. The first pdf includes plots (per protein) to show individual measurement for each peptide (peptide for DDA, transition for SRM or DIA) across runs, grouped per condition. Each peptide has a different color/type layout. Disconnected lines show that there are missing value (NA). To ignore these plots, please use the option originalPlot=FALSE. The second pdf, which is named with 'wSummarization' suffix, shows run-level summarized data per protein. The same peptides (or transition) in the first plot are presented in grey, with the summarized values (by TMP, in this example) overlaid in red. To ignore these plots with summarization, please use the option summaryPlot=FALSE.

Condition plot Condition plot visualizes potential systematic diffrences in protein inensities between conditions. Dots indicate the mean of log2 intensities for each condition. With the option interval='CI'(default), error bars indicate the confidence interval with 0.95 significant level for each condition. With the option interval='SD', error bars indicate the standard deviation among all feature intensities for each condition. The intervals are for descriptive purposes only, as more refined model-based estimation is obtained as discussed below. With the option scale=TRUE, the levels of conditions are scaled according to their labels. If scale=FALSE (default), the conditions on the x-axis are equally spaced.

dataProcessPlots has a number of layout options, including size and description of axes labels, output file name etc for three types of plots above. The option address specifies the name of the folder storing pdf files with the plots. With the option address=FALSE, plots will be shown in the graphical window, but not saved in a file. If a file with this name already exists in working directory, a suffix with a number will be appended to the file name. In this way a record of all the analyses is kept.

For more details, visit the help file using the following code.

?dataProcessPlots

4.1.4 Different imputation options

Here is the summary of combinations for imputation options with summary Method='TMP'.

- censoredInt=NULL: It assumes that all intensities are missing at random and there is no action for missing values with MBimpute=FALSE. If you have MBimpute=TRUE with censoredInt=NULL, there will be error message to fix either MBimpute or censoredInt options.
- censoredInt='NA' or '0' & MBimpute=TRUE: AFT model-based imputation using cutoffCensored value in the AFT model.
- censoredInt='NA' or '0' & MBimpute=FALSE: censored intensities (here NA's) will be replaced with the value specified in cutoffCensored.

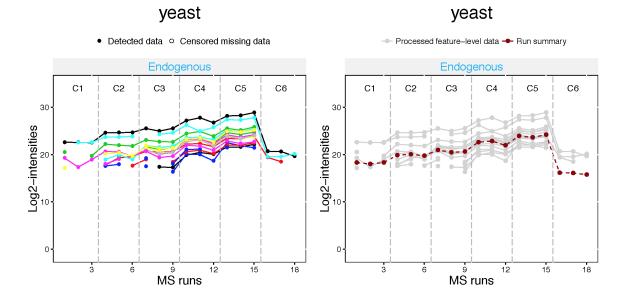

NOTE1 The default option for cutoffCensored is minFeature, taking the minimum value for the corresponding feature. With this option, those runs with substantial missing measurements will be biased by the cutoff value. In such case, you may remove the runs that have more than 50% missing values from the analysis with the option remove50missing=TRUE.

NOTE2 In case that there are completely missing measurements in a run for a protein, any imputation will not be performed. In addition, the condition, which has no measurement at all in a protein, will be not imputed.

Here is the example of dataProcess option without imputation, assuming that all missing values are random.

```
summaryMethod = 'TMP',
                                 censoredInt = NULL, MBimpute=FALSE)

##
##
    == Start the summarization per subplot...
##
##
                                                                                        1
##
    == the summarization per subplot is done.
These plots can be used compare and select among different options for imputation (e.g., TMP with or without
considering missing values for summarization in dataProcess).
dataProcessPlots(data = DDA2009.TMP, type="Profileplot", ylimUp=35,
```

featureName="NA", width=5, height=5, address="DDA2009_TMP_")

While original profile plots are the same, summarization plots reveal differences, especially for conditions 'C1' and 'C2' in 'yeast' protein, which have many missing values. Without imputation, summarized values in 'C1' group is higher than with imputation for missing values.

4.1.5 Feature selection

A feature selection module is integrated in the dataProcess function, and is performed with the option featureSubset="highQuality". In the ProcessedData element of the output returned by dataProcess, the option adds two columns feature_quality and is_outlier, to highlight uninformative features that are inconsistent with the consensus profile ("Uninformative" in feature_quality) and outliers (TRUE in is_outlier). The uninformative features and outliers can be separately investigated, curated, or removed. The option remove_uninformative_feature_outlier=TRUE removes the detected uninformative features and outliers.

```
# Feature selection
DDA2009.inf <- dataProcess(raw = DDARawData,
                            normalization = 'equalizeMedians',
                            summaryMethod = 'TMP',
                            featureSubset = "highQuality",
                            remove uninformative feature outlier = TRUE)

4.1.6 Different summarization options

Besides summarizing observations with the median polish method, MSstats also offers a summarization option using linear model with option summaryMethod="linear" with censoredInt=NULL assumes that all NA's are missing at random and uses 1m for parameter estimation.

Profile plots below can be used compare among different options for summarization (e.g., TMP with or without imputation vs linear for summarization in dataProcess).

While original profile plots are the same, summarization plots reveal differences, especially for conditions 'C1', 'C2', and 'C6' in 'yeast' protein, which have many missing values. Summarized values with linear model in these groups are much higher than those with TMP considering missing values or not.

MS runs

4.1.7 Finding differentially abundant proteins across conditions

MS runs

Comparing conditions with groupComparison With the normalized data and run-level summarized data obtained by applying one of the dataProcess summarization methods, it is of general interest to find proteins changing between groups of conditions. Within MSstats this can be done by using the groupComparison function, which takes the output of the dataProcess function as input.

```
?groupComparison
```

In addition to the processed data, the groupComparison function requires a contrast matrix to define the comparison to be made. The contrast matrix is created with each condition in column and each comparison in row. Note that the conditions are arranged in alphabetical order. The order of condition that MSstats recognizes can be shown by using levels:

```
levels(DDA2009.TMP$ProcessedData$GROUP_ORIGINAL)
```

```
## [1] "C1" "C2" "C3" "C4" "C5" "C6"
```

Entries in each row of the contrast matrix are filled in with 0, 1, or -1 to specify the comparison, where 0 is for conditions we would like to ignore, 1 is for conditions we would like to put in the numerator of the ratio or fold-change, and -1 is for conditions we would like to put in the denumerator of the ratio or fold-change.

For example, if you want to compare C2-C1, which means $\log(C2)-\log(C1)$ and the same as $\log(C2/C1)$, set '1' for C2 and '-1' for C1 in the row. Combining multiple groups for comparison is also possible. For example, if you want to compare between average of C2 and C3 and average of C1, (C3+C2)/2-C1 as formula, set '-1' for C1, '0.5' for C2 and '0.5' for C3, and '0' for rest of groups.

```
comparison1 <- matrix(c(-1,1,0,0,0,0),nrow=1)
comparison2 <- matrix(c(0,-1,1,0,0,0),nrow=1)
comparison3 <- matrix(c(0,0,-1,1,0,0),nrow=1)</pre>
```

```
comparison4 <- matrix(c(0,0,0,-1,1,0),nrow=1)
comparison5 <- matrix(c(0,0,0,0,-1,1),nrow=1)
comparison6 <- matrix(c(1,0,0,0,0,-1),nrow=1)

comparison<-rbind(comparison1,comparison2,comparison3,comparison4,comparison5,comparison6)
row.names(comparison) <- c("C2-C1","C3-C2","C4-C3","C5-C4","C6-C5","C1-C6")</pre>
```

With the contrast matrix specified, group comparison can be performed as follows.

```
DDA2009.comparisons <- groupComparison(contrast.matrix = comparison, data = DDA2009.proposed)
```

```
## |
```

Output of the groupComparison function contains three data frames:

```
# output from groupComparison function has three data frames
names(DDA2009.comparisons)
```

Results of the statistical comparison are stored in the data frame named ComparisonResult:

```
# name of columns in result data.frame
head(DDA2009.comparisons$ComparisonResult)
```

```

The result of the test for diffrential abundance is a table with columns Protein, Label (of the comparison), log2 fold change (log2FC), standard error of the log2 fold change (SE), test statistic of the Student test (Tvalue), degree of freedom of the Student test (DF), raw p-values (pvalue), p-values adjusted among all the proteins in the specific comparison using the approach by Benjamini and Hochberg (adj.pvalue). The cutoff of the adjusted p-value corresponds to the cutoff of the False Discovery Rate (Benjamini and Hochberg 1955). The positive values of log2FC for Label=C2-C1 indicate evidence in favor of C2 > C1 (i.e. proteins upregulated in C2), while the negative values indicate evidence in favor of C2 < C1 (i.e. proteins downregulated in C2), as compared to C1. The same model can be used to perform several comparisons of conditions simultaneously in the same protein.

NOTE issue column shows if there is any issue for inference in corresponding protein and comparison, for example, OneConditionMissing or CompleteMissing. If one of condition for comparison is completely missing, it would flag with OneConditionMissiong with adj.pvalue=0 and log2FC=Inf or -Inf even though pvalue=NA. For example, if you want to compare 'Condition A - Condition B', but condition B has complete missing, log2FC=Inf and adj.pvalue=0. SE, Tvalue, and pvalue will be NA. if you want to compare 'Condition A - Condition B', but condition A has complete missing, then log2FC=-Inf and adj.pvalue=0. But, please be careful for using this log2FC and adj.pvalue.

Based on the comparison results and desired significance level, a short list of the differentially abundant proteins can be obtained for further investigation:

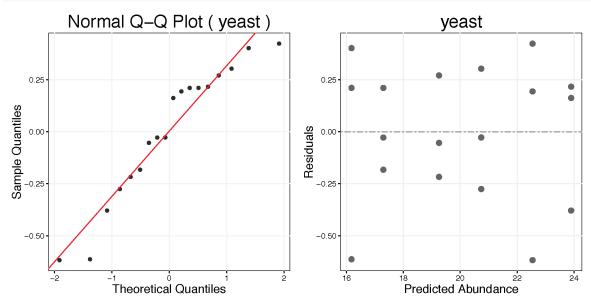

[1] 34

4.1.8 Verifying the assumption of the model

Results based on the statistical models are accurate as long as the assumptions of the models hold. Here we focus on the assumption of the Normal distribution of the measurement errors, and also on the assumption of constant variance of the measurement errors (if this option is specified in the model above). The assumptions can be checked by examining the residuals of the model fit (i.e., the deviations of the observed intensities of the transition from their model-based predictions).

modelBasedQCPlots function generates residual plots and Normal quantile-quantile plots for each protein, taking as input the results of model fitting and testing in <code>groupComparison</code>. Normal quantile-quantile plot with the option <code>type='QQPlots'</code> illustrates that such deviations from constant variance can be mistaken for deviations from Normality. Only large deviations of transition intensities from the straight line are problematic.

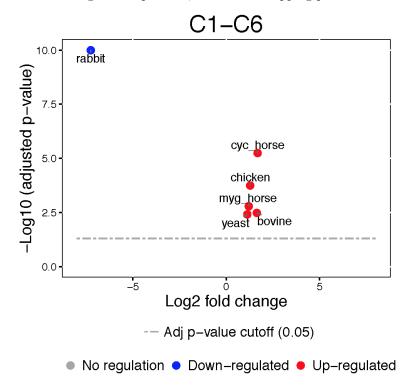

Residual plot with the option type='ResidualPlots' shows variance of the residuals that is associated with the mean feature intensity. Any specific pattern, such as increasing or decreasing by predicted abundance, is problematic.

4.1.9 Visualization of differentially abundant proteins

Volcano plots Volcano plots visualize the outcome of one comparison between conditions for all the proteins, and combine the information on statistical and practical significance. The y-axis displays the FDR-adjusted p-values on the negative log10 scale, representing statistical significance. The horizontal dashed line shows the FDR cutoff. The points above the FDR cutoff line are statistically significant proteins that are differentially abundant across conditions. These points are colored in red and blue for upregulated and downregulated proteins, respectively. The x-axis is the model-based estimate of fold change on log scale (the base of logarithm transform is the same as specified in the logTrans option of the dataProcess function), and represents practical significance. It is possible to specify a practical significance cutoff based on the estimate of fold change in addition to the statistical significance cutoff. If the fold change cutoff is specified, the points above the horizontal cutoff line but within the vertical cutoff line will be considered as not differentially abundant (and will be colored in black). The practical significance cutoff should only be applied in addition to the statistical significance cutoff (i.e., the fold change alone does not present enough evidence for differential abundance).

'VolcanoPlot.pdf' will be saved under the folder you assigned. It has the plots per comparison defined in contrast.matrix. Please check ?groupComparisonPlots for detail, such as labelling protein names, size of dots, font sizes, etc. Below is one of volcano plots, for comparison 'C1-C6' including protein name labelling. Protein name will be shown for significant proteins, without overlapping protein names each other.

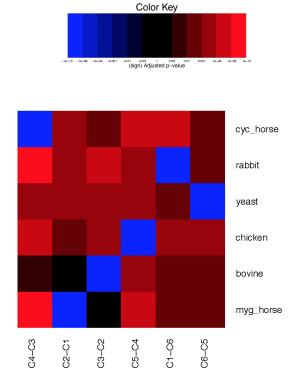

Heatmaps Heatmaps illustrate the patterns of up- and down-regulation of proteins in several comparisons. Columns in the heatmaps are comparison of conditions assigned in contrast.matrix, and rows are proteins. The heatmaps display signed FDR-adjusted p-values of the tests, colored in red/blue for significantly up-/down-regulated proteins, while taking into account the specified FDR cutoff and the additional optional fold change cutoff. Brighter colors indicate stronger evidence in favor of differential abundance. Black color represents proteins that are not significantly differentially abundant.

NOTE To draw heatmap, at least two comparisons are needed.

The rows and columns of the heatmaps can be ordered with the option clustering, which performs hierarchical clustering with the Ward method (minimum variance). The option clustering='protein' (default) clusters the rows (proteins) in the space of comparisons, based on the values of (sign of comparison) · (-log2(adjusted p-values)). The option clustering='comparison' clusters the columns in the space of proteins, based on the values of (sign of comparison) · (-log2(adjusted p-value)). The option clustering='both reorders both columns and rows.

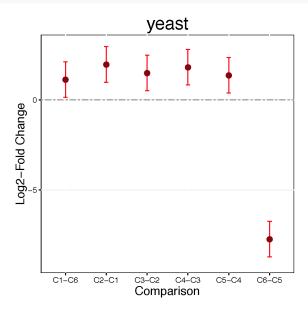

```
groupComparisonPlots(data = DDA2009.comparisons$ComparisonResult, type = 'Heatmap')
```

'Heatmap.pdf' will be saved under the folder you assigned. Below is one example, showing the results for several comparisons simultaneously.

Comparison plots Comparison plots illustrate model-based estimates of log-fold changes, and the associated uncertainty, in several comparisons of conditions for one protein. X-axis is the comparison of interest. Y-axis is the log fold change. The dots are the model-based estimates of log-fold change, and the error bars are the model-based 95% confidence intervals (the option sig can be used to change the significance level of significance). For simplicity, the confidence intervals are adjusted for multiple comparisons within protein only, using the Bonferroni approach. For proteins with N comparisons, the individual confidence intervals are at the level of 1-sig/N.

For further details, such as labelling protein names, size of dots, font sizes, etc., visit the help file using the following code.

?groupComparisonPlots

4.1.10 Sample size calculation for a future experiment

This last analysis step views the dataset as a pilot study of a future experiment, utilizes its variance components, and calculates the minimal number of replicates required in a future experiment to achieve the desired statistical power. The calculation is performed by the function designSampleSize, which takes as input the fitted model in groupComparison. Sample size calculation assumes same experimental design (i.e. group comparison, time course or paired design) as in the current dataset, and uses the model fit to estimate the median variance components across all the proteins. Finally, sample size calculation assumes that a large proportion of proteins (specifically, 99%) will not change in abundance in the future experiment. This assumption also provides conservative results. Using the estimated variance components, the function relates the number of biological replicates per condition (numSample, rounded to 0 decimal), average statistical power across all the proteins (power), minimal fold change that we would like to detect (can be specified as a range, e.g. desiredFC=c(1.1, 2)), and the False Discovery Rate (FDR). The user should specify all these quantities but one, and the function will solve for the remainder. The quantity to solve for should be set to = TRUE.

?designSampleSize

Visualization of sample size calculations The calculated relationship between the number of biological replicates per condition (numSample), average statistical power across all the proteins (power), minimal fold change that we would like to detect (desiredFC), and the False Discovery Rate (FDR) can be visualized using the function designSampleSizePlots. The function takes as input the output of designSampleSize.

For further details, visit the help file using the following code.

?designSampleSizePlots

4.1.11 Quantification of protein abundance in individual samples or conditions

Many downstream analysis steps (such as clustering or classification of individual samples in the space of their protein profiles) require summary values of protein abundance in each biological replicate or in each condition, on a relative scale that is comparable between runs.

dataProcess function performs model-based run-level summarization. quantification function enables subject-level summarization or group-level summarization with the run-level summarization from dataProcess.

The option, type='sample'(default), performs sample quantification, i.e. it outputs the estimates of relative protein abundance in each biological replicate. If there are technical replicates for biological replicates, sample quantification will be the median among technical replicates. If there is no technical replicate for biological replicate (sample), sample quantification will be the same as run-level summarization. In presence of completely missing values in biological replicate, the estimates will be zero.

The option type='group' performs group quantification, i.e. it outputs the estimates of relative protein abundance in each condition, summarized over the biological replicates (median among sample quantification). In presence of completely missing values in a condition, the estimates will be zero.

MSstats supports two output formats. The option format='matrix' (default) outputs an array where rows are proteins, and columns are conditions (for group quantification), or combinations of biological replicate and condition ids (for sample quantification). The option format='long' produces an array where each row corresponding to relative protein abundances, and columns are Protein, Condition, LogIntensities (and BioReplicate in the case of sample quantification).

4.2 Suggested workflow with Skyline output for DDA

This section describes steps and considerations to properly format data processed by Skyline, prior to the MSstats analysis. In the following example, the raw files for the benchmark dataset (Choi, M. and Eren-Dogu, Z. F. and Colangelo, C. and Cottrell, J. and Hoopmann, M. R. and Kapp, E. A. and Kim, S. and Lam, H. and Neubert, T. A. and Palmblad, M. and Phinney, B. S. and Weintraub, S. T. and MacLean, B. and Vitek, O. 2017) are used. Dataset was processed and quantified with Skyline (3.5.0.9319). Details for data processing are described in Choi, et al., 2017 and Panorama Web https://panoramaweb.org/iPRG-2015.url for iProphet cut-off 0.15. The datasets and details for data processing are available in MassIVE.quant, MSV000079843, Reanalysis: RMSV000000249.1

4.2.1 Load Skyline output

This required input data is generated automatically when using MSstats report format in Skyline. We first load and access the dataset processed by Skyline. The name of saved file from Skyline using MSstats report format is 'Choi2017_DDA_Skyline_input.csv' under the folder named dda_skyline.

```
# Read output from skyline
raw <- read.csv("dda_skyline/Choi2017_DDA_Skyline_input.csv")</pre>
```

We can read csv file. Here we will load R data file which is the exactly same data in Choi2017_DDA_Skyline_input.csv file.

```
# Load R data, which is convered from csv file, output from skyline
load("dda_skyline/iprg.skyline.rda")
raw <- iprg.skyline
head(raw)</pre>
```

Annotation information is required to fill in Condition and BioReplicate for corresponding Run information. Users have to prepare as csv or txt file like 'Choi2017_DDA_Skyline_annotation.csv', which includes Run, Condition, and BioReplicate information, and load it in R.

```
annot <- read.csv("dda_skyline/Choi2017_DDA_Skyline_annotation.csv", header=TRUE)
annot</pre>
```

```

4.2.2 Preprocessing with DDA experiment from Skyline output

The input data for MSstats is required to contain variables of ProteinName, PeptideSequence, PrecursorCharge, FragmentIon, ProductCharge, IsotopeLabelType, Condition, BioReplicate, Run, Intensity. These variable names should be fixed. MSstats input from Skyline adapts the column scheme of the dataset so that it fits MSstats input format. However there are several extra column names and also some of them need to be changed. SkylinetoMSstatsFormat function helps pre-processing for making right format of MSstats input from Skyline output. For example, it renames some column name, and replace truncated peak intensities with NA. Another important step is to handle isotopic peaks before using dataProcess. The output from Skyline for DDA experiment has several measurements of peak area from the monoisotopic, M+1 and M+2 peaks. To get a robust measure of peptide intensity, we can sum over isotopic peaks per peptide or use the highest peak. Here we take a summation per peptide ion.

Here is the summary of pre-processing steps in SkylinetoMSstatsFormat function.

SkylinetoMSstatsFormat

- Rename column names
- Remove decoy proteins and iRT peptides
- Remove shared peptides
- Replace NA for truncated intensities
- DDA: Sum of isotopic peaks per peptide and charge
- DIA: filter by q-value
- Remove features with all missing values or with less than 3 measurements across MS runs
- Remove protein with only one feature
- Add annotation for experimental design : Group, biological replicate, fraction information per MS run

Options for SkylinetoMSstatsFormat

- annotation: name of 'annotation.txt' or 'annotation.csv' data which includes Condition, BioReplicate, and Run. If annotation is already complete in Skyline, use annotation=NULL (default). It will use the annotation information from input.
- removeiRT : TRUE (default) will remove the proteins or peptides which are labeld 'iRT' in 'StandardType' column. FALSE will keep them.
- filter_with_Qvalue: TRUE (default) will filter out the intensities that have greater than qvalue_cutoff in DetectionQValue column. Those intensities will be replaced with zero and will be considered as censored missing values for imputation purpose.
- qvalue_cutoff : Cutoff for DetectionQValue. Default is 0.01.
- useUniquePeptide: TRUE (default) removes peptides that are assigned for more than one proteins. We assume to use unique peptide for each protein.
- \bullet $\ \mathbf{fewMeasurement}$: remove or keep the feature w with few measurements.
 - 'remove': (default) remove the features that have 1 or 2 measurements across runs.
 - 'keep': keep all the features. However, it could generate the error in the step for fitting the statistical model.
- removeOxidationMpeptides: TRUE will remove the peptides including 'oxidation (M)' in modification. FALSE is default.
- **removeProtein_with1Feature** : TRUE will remove the proteins which have only 1 peptide and charge. FALSE is default.

For further details, visit the help file using the following code.

?SkylinetoMSstatsFormat

Now, we use SkylinetoMSstatsFormat function for this example dataset. We chose to remove the proteins with only 1 peptide ion.

** Proteins, which names include DECOY, are removed.

```
## ** Peptides, that are used in more than one proteins, are removed.
## Warning in SkylinetoMSstatsFormat(raw, annotation = annot,
## removeProtein_with1Feature = TRUE): NAs introduced by coercion
## ** Truncated peaks are replaced with NA.
## ** For DDA datasets, three isotopic peaks per feature and run are summed.
## ** 4 features have all NAs or zero intensity values and are removed.
## ** 13 features have 1 or 2 intensities across runs and are removed.
## ** All proteins have at least two features.
```

This function shows the progress. The output of SkylinetoMSstatsFormat, called quant, is ready for next step.

head(quant)

4.2.3 Different options for Skyline in dataProcess

The difference between output from Skyline and other spectral processing tool is that Skyline distinguishes random missing (NA) by technical issues and low noisy intensity due to less than limit of etection. The output from Skyline can have both NA (expect small number of NAs or none of them) and very small intensity close to zero (less than 1 in intensity) and those should be treated different types of missing. In dataProcess, users need to use censoredInt='0' for Skyline output, which means to distinguish between NA as random missing and 0 as censored missing.

Further steps is the same as in general workflow (section 4.1).

4.3 Suggested workflow with MaxQuant output for DDA

The following R code chunks show steps to format a MaxQuant output for analysis by MSstats. In the following example, the raw files for the benchmark dataset (Choi, M. and Eren-Dogu, Z. F. and Colangelo, C. and Cottrell, J. and Hoopmann, M. R. and Kapp, E. A. and Kim, S. and Lam, H. and Neubert, T. A. and Palmblad, M. and Phinney, B. S. and Weintraub, S. T. and MacLean, B. and Vitek, O. 2017) are used. MS/MS spectra were searched using MaxQuant (v1.5.1.2) and Andromeda as search engine. The datasets and details for data processing are available in MassIVE.quant, MSV000079843, Reanalysis: RMSV000000249.2

4.3.1 Load MaxQuant outputs

Three files should be prepared before MSstats. Two files, 'proteinGroups.txt' and 'evidence.txt' are outputs from MaxQuant.

```
## First, get protein ID information
proteinGroups <- read.table("dda_maxquant/Choi2017_DDA_MaxQuant_proteinGroups.txt", sep = "\t", header
## Read in MaxQuant file: evidence.txt
infile <- read.table("dda_maxquant/Choi2017_DDA_MaxQuant_evidence.txt", sep = "\t", header = TRUE)</pre>
```

One file is for annotation information, required to fill in Condition and BioReplicate for corresponding Run information. Users have to prepare as csv or txt file like 'Choi2017_DDA_MaxQuant_annotation.csv', which includes Run, Condition, and BioReplicate information, and load it in R.

```
## Read in annotation including condition and biological replicates: annotation.csv
annot <- read.csv("dda_maxquant/Choi2017_DDA_MaxQuant_annotation.csv", header = TRUE)
annot</pre>
```

```

4.3.2 Preprocessing with DDA experiment from MaxQuant output

MaxQtoMSstatsFormat function helps pre-processing for making right format of MSstats input from MaxQuant output. Basically, this function gets peptide ion intensity from 'evidence.txt' file. In addition, there are several steps to filter out or to modify the data in order to get required information.

Here is the summary of pre-processing steps in MaxQtoMSstatsFormat function.

MaxQtoMSstatsFormat

- Remove `+` contaminant, reverse, Only.identified.by.site proteins
- Use 'protein.IDs' in proteinGroups.txt
- Extract essential information(columns)
- Remove shared peptides
- Aggregate multiple measurement per feature and run
- Remove features with all missing values or with less than 3 measurements across MS runs
- Remove protein with only one feature
- Add annotation for experimental design : Group, biological replicate, fraction information per MS run

Options for MaxQtoMSstatsFormat

- evidence: name of 'evidence.txt' data, which includes feature-level data
- proteinGroups: name of 'proteinGroups.txt' data. It needs to matching protein group ID. If proteinGroups=NULL, use 'Proteins' column in 'evidence.txt'.
- annotation :name of 'annotation.txt' or 'annotation.csv' data which includes Raw.file, Condition, BioReplicate, Run, and IsotopeLabelType information.
- proteinID: which column in evidence.txt will be used for ProteinName in MSstats.
 - 'Proteins': (default) Proteins column will be used.
 - 'Leading.razor.protein': Leading.razor.protein column will be used.
- useUniquePeptide: TRUE (default) removes peptides that are assigned for more than one proteins. We assume to use unique peptide for each protein.
- summaryforMultipleRows: max(default), sum, or mean. MSstats assumes that there is only one measurement (peak intensity) for one feature and one run. When there are multiple measurements for certain feature and certain run, MSstats need to know which measurements need to be used for further analysis. Users can use highest(max), sum or mean among multiple measurements for one feature and one run.
- \bullet $\ \mathbf{fewMeasurement}$: remove or keep the feature w with few measurements.
 - 'remove': (default) remove the features that have 1 or 2 measurements across runs.
 - 'keep': keep all the features. However, it could generate the error in the step for fitting the statistical model.
- removeMpeptides: TRUE will remove the peptides including 'M' sequence. FALSE is default.
- removeOxidationMpeptides: TRUE will remove the peptides including 'oxidation (M)' in modification. FALSE is default.
- removeProtein_with1Peptide: TRUE will remove the proteins which have only 1 peptide and charge. FALSE is default.

For further details, visit the help file using the following code.

```
\hbox{\it \#\# check options for converting format}\\ \hbox{\it ?MaxQtoMSstatsFormat}
```

Now, we use MaxQtoMSstatsFormat function for this example dataset. We chose to remove the proteins with only 1 peptide ion.

```
## ** + Contaminant, + Reverse, + Only.identified.by.site, proteins are removed.
```

** Peptide and charge, that have 1 or 2 measurements across runs, are removed.

** 282 proteins, which have only peptide and charge in a protein, are removed among 3157 proteins.

This function shows the progress. The output of MaxQtoMSstatsFormat, called quant, is ready for next step.

```
## now 'quant' is ready for MSstats
head(quant)
```

4.3.3 Different options for MaxQuant in dataProcess

MaxQuant has certain or fixed threshold for intensity value internally as an parameter. Intensities less than the threshold are reported as NA. All missing values are NA in output from MaxQuant. In dataProcess, users need to use censoredInt='NA'. Users can used the same choice for other options.

Further steps is the same as in general workflow (section 4.1).

4.4 Suggested workflow with Progenesis output for DDA

This section describes steps and considerations to properly format data processed by Progenesis, prior to the MSstats analysis. In the following example, the raw files for the benchmark dataset (Choi, M. and Eren-Dogu, Z. F. and Colangelo, C. and Cottrell, J. and Hoopmann, M. R. and Kapp, E. A. and Kim, S. and Lam, H. and Neubert, T. A. and Palmblad, M. and Phinney, B. S. and Weintraub, S. T. and MacLean, B. and Vitek, O. 2017) are used. Peptide features were identified with the Progenesis algorithm (v4.0.6403), aligned across all files, and annotated with the peptide identification resulting from the database search result

from Comet. The datasets and details for data processing are available in MassIVE.quant, MSV000079843, Reanalysis: RMSV000000249.3

4.4.1 Load Progenesis output

Here is the expected input for MSstats, which is output of Progenesis.

```
## First, read output of Progenesis
raw <- read.csv("dda_progenesis/Choi2017_DDA_Progenesis_input.csv")</pre>
head(raw)

4.4.2 Preprocessing with DDA experiment from progenesis output

The output from Progenesis includes peptide ion-level quantification for each MS runs. ProgenesistomstatsFormat function helps pre-processing for making right format of MSstats input from Progenesis output. Basically, this function reformats wide format to long format. It provide 'Raw.abundance', 'Normalized.abundance' and 'Spectral count' columns. This converter uses 'Raw.abundance' columns for Intensity values. In addition, there are several steps to filter out or to modify the data in order to get required information.

Here is the summary of pre-processing steps in ProgenesistoMSstatsFormat function.

ProgenesistoMSstatsFormat

- Extract essential information(columns)
- Subset the rows with `use in quantitation = true`
- Rename column names
- Remove empty protein and peptide sequence
- Remove duplicated measurements
- Remove shared peptides
- Aggregate multiple measurements per feature and run
- Remove features with all missing values or with less than 3 measurements across MS runs
- Remove protein with only one feature
- Add annotation for experimental design : Group, biological replicate, fraction information per MS run

Options for ProgenesistoMSstatsFormat

- input: name of Progenesis output, which is wide-format. 'Accession', 'Sequence', 'Modification', 'Charge' and one column for each run are required. 'Accession' column is used for ProteinName. 'Raw.abundance' is used for Intensity.
- annotation :name of 'annotation.txt' or 'annotation.csv' data which includes Condition, BioReplicate, and Run information. It will be matched with the column name of input for MS runs.
- useUniquePeptide: TRUE (default) removes peptides that are assigned for more than one proteins. We assume to use unique peptide for each protein.
- summaryforMultipleRows: max(default), sum, or mean. MSstats assumes that there is only one measurement (peak intensity) for one feature and one run. When there are multiple measurements for certain feature and certain run, MSstats need to know which measurements need to be used for further analysis. Users can use highest(max), sum or mean among multiple measurements for one feature and one run.
- **fewMeasurement**: remove or keep the featurew with few measurements.
 - 'remove': (default) remove the features that have 1 or 2 measurements across runs.
 - 'keep': keep all the features. However, it could generate the error in the step for fitting the statistical model.
- removeOxidationMpeptides: TRUE will remove the peptides including 'oxidation (M)' in modification. FALSE is default.
- removeProtein_with1Peptide: TRUE will remove the proteins which have only 1 peptide and charge. FALSE is default.

For further details, visit the help file using the following code.

```
## check options for converting format
?ProgenesistoMSstatsFormat
```

Now, we use ProgenesistoMSstatsFormat function for this example dataset. We chose to remove the proteins only 1 peptide ion.

This function shows the progress. The output of ProgenesistoMSstatsFormat, called quant, is ready for next step.

```
## now 'quant' is ready for MSstats
head(quant)
```

4.4.3 Different options for Progenesis in dataProcess

Progenesis reports 0(zero) for missing values and does not have NA. Therefore,in dataProcess, users need to use censoredInt='0'. Users can used the same choice for other options.

Further steps is the same as in general workflow (section 4.1).

4.5 Suggested workflow with Proteome Discoverer output for DDA

This section describes steps and considerations to properly format data processed by Proteome Discoverer, prior to the MSstats analysis. In the following example, another spike-in dataset processed by Proteome Discoverer is used to demonstrate. The datasets and details for data processing are available in MassIVE.quant, MSV000084181, Reanalysis: RMSV00000261.4

4.5.1 Load Proteome Discoverer output

3

13

The output from Proteome Discoverer includes several level of datasets. PSM sheet should be saved as csv as below. Here is the expected input for MSstats.

```
## Read PSM-level data
raw <- read.csv("dda_PD/ControlMixture_DDA_ProteomeDiscoverer_input.csv")</pre>
head(raw)

One file is for annotation information, required to fill in Condition and BioReplicate for corresponding Run information. Users have to prepare as csv or txt file like 'ControlMixture_DDA_ProteomeDiscoverer_annotation.csv', which includes Run, Condition, and BioReplicate information, and load it in R.

Read in annotation including condition and biological replicates
annot <- read.csv("dda_PD/ControlMixture_DDA_ProteomeDiscoverer_annotation.csv", header = TRUE)
annot</pre>

```

4.5.2 Preprocessing with DDA experiment from Proteome Discoverer output

PDtoMSstatsFormat function helps pre-processing for making right format of MSstats input from Proteome Discoverer output. Protein.Group.Accessions is used for ProteinName. The combination of Sequence and Modifications is used for PeptideSequence. Charge is used for PrecursorCharge. Precursor.Area is used for Intensity. In addition, there are several steps to filter out or to modify the data in order to get required information.

Here is the summary of pre-processing steps in PDtoMSstatsFormat function.

PDtoMSstatsFormat

- Extract essential information(columns)
- Rename column names
- Remove shared peptides
- Aggregate multiple measurements per feature and run : max or mean
- Remove features with all missing values or with less than 3 measurements across MS runs
- Remove protein with only one feature(Peptide ion)
- Add annotation for experimental design : Group, biological replicate, fraction information per MS run

Options for PDtoMSstatsFormat

- input: name of Proteome discover PSM output, which is long-format. "Protein.Group.Accessions", "#Proteins", "Sequence", "Modifications", "Charge", "Intensity", "Spectrum.File" are required.
- annotation: name of 'annotation.txt' or 'annotation.csv' data which includes Condition, BioReplicate, and Run information. 'Run' will be matched with 'Spectrum.File'.
- useNumProteinsColumn : TRUE removes peptides which have more than 1 in # Proteins column of PD output.
- useUniquePeptide: TRUE (default) removes peptides that are assigned for more than one proteins. We assume to use unique peptide for each protein.
- summaryforMultipleRows: max(default), sum, or mean. MSstats assumes that there is only one measurement (peak intensity) for one feature and one run. When there are multiple measurements for certain feature and certain run, MSstats need to know which measurements need to be used for further analysis. Users can use highest(max), sum or mean among multiple measurements for one feature and one run.
- **fewMeasurement** : remove or keep the featurew with few measurements.
 - 'remove': (default) remove the features that have 1 or 2 measurements across runs.
 - 'keep': keep all the features. However, it could generate the error in the step for fitting the statistical model.
- removeOxidationMpeptides: TRUE will remove the modified peptides including 'Oxidation (M)' in 'Modifications' column. FALSE is default.
- removeProtein_with1Peptide: TRUE will remove the proteins which have only 1 peptide and charge. FALSE is default.

- which quantification: Use 'Precursor.Area' (default) column for quantified intensities. 'Intensity' or 'Area' can be used instead.
- which.proteinid: Use 'Protein.Accessions' (default) column for protein name. 'Master.Protein.Accessions' can be used instead.
- which.sequence: Use 'Sequence' (default) column for peptide sequence. 'Annotated.Sequence' can be used instead.

For further details, visit the help file using the following code.

```
## check options for converting format
?PDtoMSstatsFormat
```

Now, we use PDtoMSstatsFormat function for this example dataset. We chose to remove the proteins with only 1 peptide ion.

- ## ** Multiple measurements in a feature and a run are summarized by summaryforMultipleRows.
- ## ** 633 features have all NAs or zero intensity values and are removed.
- ## ** 241 proteins, which have only one feature in a protein, are removed among 1512 proteins.

This function shows the progress. The output of PDtoMSstatsFormat, called quant, is ready for next step.

head(quant)

4.5.3 Different options for Proteome Discoverer in dataProcess

Progenesis reports NA for missing values. Therefore,in dataProcess, users need to use censoredInt='NA'. Users can used the same choice for other options.

Further steps is the same as in general workflow (section 4.1).

4.6 Suggested workflow with OpenMS output for DDA

This section describes steps and considerations to properly format data processed by OpenMS, prior to the MSstats analysis. In the following example, the raw files for the benchmark dataset (Choi, M. and Eren-Dogu, Z. F. and Colangelo, C. and Cottrell, J. and Hoopmann, M. R. and Kapp, E. A. and Kim, S. and Lam, H. and Neubert, T. A. and Palmblad, M. and Phinney, B. S. and Weintraub, S. T. and MacLean, B. and Vitek, O. 2017) are used. The datasets and details for data processing are available in OpenMS webpage, iPRG 2015 example dataset

4.6.1 Load OpenMS output

Here is the expected input for MSstats, which is output of OpenMS.

```
## Read PSM-level data
raw <- read.csv("dda_openms/iPRG_lfq_input_MSstats.csv")
head(raw)</pre>
```

##		ProteinName	PeptideSequence	Pred	cursorCharge	Fragn	mentIon
##	1	sp P09938 RIR2_YEAST	AAADALSDLEIK		2		NA
##	2	sp P09938 RIR2_YEAST	AAADALSDLEIK		2		NA
##	3	sp P09938 RIR2_YEAST	AAADALSDLEIK		2		NA
##	4	sp P09938 RIR2_YEAST	AAADALSDLEIK		2		NA
##	5	sp P09938 RIR2_YEAST	AAADALSDLEIK		2		NA
##	6	sp P09938 RIR2_YEAST	AAADALSDLEIK		2		NA
##		ProductCharge Isotope	eLabelType Condi	tion	BioReplicate	Run	Intensity
##	1	0	L	1	1	. 1	391797000
##	2	0	L	4	10	10	103656000
##	3	0	L	4	11	11	361107000
##	4	0	L	1	2	2	456756000
##	5	0	L	1	3	3	389268000
##	6	0	L	2	4	. 4	433488000

If you follow the workflow in OpenMS KNIME, annotation information should be already filled in.

4.6.2 Preprocessing with DDA experiment from OpenMS output

OpenMStoMSstatsFormat function helps pre-processing for making right format of MSstats input from OpenMS output.

Here is the summary of pre-processing steps in OpenMStoMSstatsFormat function.

OpenMStoMSstatsFormat

- Extract essential information(columns)
- Rename column names
- Remove shared peptides
- Aggregate multiple measurements per feature and run
- Remove features with all missing values or with less than 3 measurements across MS runs
- Remove protein with only one feature
- Add annotation for experimental design : Group, biological replicate, fraction information per MS run

Options for OpenMStoMSstatsFormat

- input: name of MSstats input report from OpenMS, which includes feature(peptide ion)-level data.
- annotation: name of 'annotation.txt' data which includes Raw.file, Condition, BioReplicate, and Run information. If annotation is already complete in OpenMS, use annotation=NULL (default). It will use the annotation information from input.
- useUniquePeptide: TRUE (default) removes peptides that are assigned for more than one proteins. We assume to use unique peptide for each protein.
- summaryforMultipleRows: max(default), sum, or mean. MSstats assumes that there is only one measurement (peak intensity) for one feature and one run. When there are multiple measurements for certain feature and certain run, MSstats need to know which measurements need to be used for further analysis. Users can use highest(max), sum or mean among multiple measurements for one feature and one run.
- **fewMeasurement**: remove or keep the featurew with few measurements.
 - 'remove': (default) remove the features that have 1 or 2 measurements across runs.
 - 'keep': keep all the features. However, it could generate the error in the step for fitting the statistical model.
- removeProtein_with1Feature : TRUE will remove the proteins which have only 1 peptide and charge. FALSE is default.

For further details, visit the help file using the following code.

```
## check options for converting format
?OpenMStoMSstatsFormat
```

Now, we use OpenMStoMSstatsFormat function for this example dataset. We chose to remove the proteins with shared peptides or only 1 peptide ion.

- ## ** O features have all NAs or zero intensity values and are removed.
- ## ** All peptides are unique peptides in proteins.
- ## ** 909 features have 1 or 2 intensities across runs and are removed.
- ## ** 698 proteins, which have only one feature in a protein, are removed among 2538 proteins.
- ## ** No multiple measurements in a feature and a run.

```
## Warning in OpenMStoMSstatsFormat(raw, removeProtein_with1Feature = TRUE): NAs
## introduced by coercion
```

This function shows the progress. The output of OpenMStoMSstatsFormat, called quant, is ready for next step.

```
## now 'quant' is ready for MSstats
head(quant)
```

4.6.3 Different options for OpenMS in dataProcess

Progenesis reports NA for missing values. Therefore,in dataProcess, users need to use censoredInt='NA'. Users can used the same choice for other options.

Further steps is the same as in general workflow (section 4.1).

5. DIA analysis with MSstats

5.1 Suggested workflow with Skyline output for DIA

The analysis for DIA with Skyline output is the same as the workflow with Skyline output for DDA. Please check section 4.2 and options form SkylinetoMSstatsFormat.

5.2 Suggested workflow with Spectronaut output for DIA

This section describes steps and considerations to properly format data processed by Spectronaut for SWATH/DIA experiments, prior to the MSstats analysis. In the following example, the raw files for the

benchmark dataset (Bruderer et al. 2015) are quantified by Spectronaut. The datasets and details for data processing are available in MassIVE.quant, MSV000081828, Reanalysis: RMSV000000252.2

5.2.1 Load Spectronaut output

We first load and access the dataset processed by Spectronaut.

```
# Read output from Spectronaut
raw <- read.csv("dia_spectronaut/Bruderer2015_DIA_Spectronaut_input.xls", sep="\t")</pre>
```

One file is for annotation information, required to fill in Condition and BioReplicate for corresponding Run information. Users have to prepare as csv or txt file like 'Bruderer2015_DIA_Spectronaut_annotation.csv', which includes Run, Condition, and BioReplicate information, and load it in R.

```
## Read in annotation including condition and biological replicates
annot <- read.csv("dia_spectronaut/Bruderer2015_DIA_Spectronaut_annotation.csv", header = TRUE)
annot</pre>
```

```
##

```

The input data for MSstats is required to contain variables of ProteinName, PeptideSequence, PrecursorCharge, FragmentIon, ProductCharge, IsotopeLabelType, Condition, BioReplicate, Run, Intensity. These variable names should be fixed. Therefore, we need to get subset of useful columns and to rename them. Also several filtering steps are required. SpectronauttoMSstatsFormat function helps pre-processing for making right format of MSstats input from Spectronaut output. First, it uses only noloss from F.FrgLossType. If not, multiple measurements for each feature and run can be happend. Spectronaut provides the column named F.ExcludedFromQuantification based on XIC quality such as interference between chromatographies. Only features with F.ExcludedFromQuantification == 'False' should be used. PG.ProteinGroups is used for ProteinName. EG.ModifiedSequence is used for PeptideSequence. FG.Charge is used for PrecursorCharge. F.FrgIon is used for FragmentIon. F.Charge is used for ProductCharge. F.PeakArea with default option is used for Intensity. Then several filtering steps will be performed.

Here is the summary of pre-processing steps for SWATH/DIA experiment in SpectronauttoMSstatsFormat function.

SpectronauttoMSstatsFormat

- Extract essential information(columns)
- Use only 'noloss' in F.FrgLossType
- Filter by PG.Qvalue
- Remove shared peptides
- Aggregate multiple measurements per feature and run
- Remove features with all missing values or with less than 3 measurements across MS runs
- Remove protein with only one feature
- Add annotation for experimental design : Group, biological replicate, fraction information per MS run

This function shows the progress. The output of SpectronauttoMSstatsFormat, called quant, is ready for next step.

```
## now 'quant' is ready for MSstats

5.2.3 Different options for Spectronaut output of DIA experiment in dataProcess

174551.3

In dataProcess, users need to use censoredInt='0' for Spectronaut output. Spectronaut output generates very few number of NA. After applying Qvalue, zero intensities will be generated and those should be imputed.

Further steps is the same as in general workflow (section 4.1).

6 B_D140314_SGSDSsample1_R01_MHRM

5.3 Suggested workflow with DIA-Umpire output for DIA

This section describes steps and considerations to properly format data processed by DIA-Umpire for SWATH/DIA experiments, prior to the MSstats analysis. In the following example, the raw files for the benchmark dataset (Bruderer et al. 2015) are quantified by DIA-Umpire. The datasets and details for data processing are available in MassIVE.quant, MSV000081828, Reanalysis: RMSV000000252.3

5.3.1 Load DIA-Umpire output

We first load and access the dataset processed by DIA-Umpire.

```
# Read output from DIA_Umpire : three output from different levels.
raw.frag <- read.csv('dia_diaumpire/Bruderer2015_DIA_DIAumpire_input_FragSummary.xls', sep="\t")
raw.pep <- read.csv('dia_diaumpire/Bruderer2015_DIA_DIAumpire_input_PeptideSummary.xls', sep="\t")
raw.pro <- read.csv('dia_diaumpire/Bruderer2015_DIA_DIAumpire_input_ProtSummary.xls', sep="\t")
One file is for annotation information, required to fill in Condition and BioReplicate for corresponding Run
information. Users have to prepare as csv or txt file like 'Bruderer2015 DIA DIAumpire annotation.csv',
which includes Run, Condition, and BioReplicate information, and load it in R.
## Read in annotation including condition and biological replicates
annot <- read.csv("dia_diaumpire/Bruderer2015_DIA_DIAumpire_annotation.csv", header = TRUE)
annot
##
         Condition BioReplicate
                                                                Run

```

5.3.2 Preprocessing with DIA experiment from DIA-Umpire output

Here is the summary of pre-processing steps for DIA experiment in DIAUmpiretoMSstatsFormat function.

DIAUmpiretoMSstatsFormat

- Get selected fragments from DIA-Umpire
- Get selected peptides from DIA-Umpire
- Subtract the peak intensities for selected peptides and fragments
- Change the data format
- Remove shared peptides
- Aggregate multiple measurements per feature and run
- Remove features with all missing values or with less than 3 measurements across MS runs
- Remove protein with only one feature
- Add annotation for experimental design : Group, biological replicate, fraction information per MS run

${\bf Options} \ {\bf for} \ {\tt DIAUmpiretoMSstatsFormat}$

- raw.frag: name of FragSummary_date.xls data, which includes feature-level data.
- raw.pep: name of PeptideSummary_date.xls data, which includes selected fragments information.
- raw.pro: name of ProteinSummary_date.xls data, which includes selected peptides information.
- annotation: name of 'annotation.txt' data which includes Raw.file, Condition, BioReplicate, and Run information.
- useSelectedFrag : TRUE (default) will use the selected fragment for each peptide. 'Selected_fragments' column is required.
- useSelectedPep: TRUE (default) will use the selected peptide for each protein. 'Selected_peptides' column is required.
- summaryforMultipleRows: max(default), sum, or mean. MSstats assumes that there is only one measurement (peak intensity) for one feature and one run. When there are multiple measurements for certain feature and certain run, MSstats need to know which measurements need to be used for further analysis. Users can use highest(max), sum or mean among multiple measurements for one feature and one run
- **fewMeasurement**: remove or keep the featurew with few measurements.
 - 'remove': (default) remove the features that have 1 or 2 measurements across runs.
 - 'keep': keep all the features. However, it could generate the error in the step for fitting the statistical model.
- removeProtein_with1Feature : TRUE will remove the proteins which have only 1 feature, which is the combination of peptide, precursor charge, fragment and charge. FALSE is default.

For further details, visit the help file using the following code.

** Got the selected fragments.

```
## ** Extract the data from selected fragments and/or peptides.
## ** 0 features have all NAs or zero intensity values and are removed.
## ** 10824 features have 1 or 2 intensities across runs and are removed.
## ** 26 proteins, which have only one feature in a protein, are removed among 3645 proteins.
```

This function shows the progress. The output of DIAUmpiretoMSstatsFormat, called quant, is ready for next step.

** No multiple measurements in a feature and a run.

```
## now 'quant' is ready for MSstats
head(quant)
```

```

One file is for annotation information, required to fill in Condition and BioReplicate for corresponding Run information. Users have to prepare as csv or txt file like 'Rost2014_DIA_OpenSWATH_annotation.csv', which includes Run, Condition, and BioReplicate information, and load it in R.

Read in annotation including condition and biological replicates: ControlMixture_DDA_ProteomeDiscove
annot <- read.csv("dia_openswath/Rost2014_DIA_OpenSWATH_annotation.csv", header = TRUE)
annot</pre>

5.4.2 Preprocessing with DIA experiment from OpenSWATH output

The output from OpenSWATH should look like below.

head(raw)

Here is the summary of pre-processing steps for SWATH/DIA experiment in OpenSWATHtoMSstatsFormat function.

OpenSWATHtoMSstatsFormat

- Remove the decoys
- Filter by m_score
- Change data format
- Remove shared peptides
- Aggregate multiple measurements per feature and run : max or mean
- Remove features with all missing values or with less than 3 measurements across MS runs
- Remove protein with only one feature
- Add annotation for experimental design : Group, biological replicate, fraction information per MS run

Options for OpenSWATHtoMSstatsFormat

- input: name of MSstats input report from OpenSWATH, which includes feature-level data.
- annotation :name of 'annotation.txt' data which includes Raw.file, Condition, BioReplicate, and Run information. Run should be the same as 'filename'.
- filter_with_mscore: TRUE (default) will filter out the features that have greater than mscore_cutoff in m score column. Those features will be removed.
- mscore_cutoff: Cutoff for m_score. default is 0.01.
- useUniquePeptide: TRUE (default) removes peptides that are assigned for more than one proteins. We assume to use unique peptide for each protein.
- summaryforMultipleRows: max(default), sum, or mean. MSstats assumes that there is only one measurement (peak intensity) for one feature and one run. When there are multiple measurements for certain feature and certain run, MSstats need to know which measurements need to be used for further analysis. Users can use highest(max), sum or mean among multiple measurements for one feature and one run.
- **fewMeasurement**: remove or keep the featurew with few measurements.
 - 'remove': (default) remove the features that have 1 or 2 measurements across runs.
 - 'keep': keep all the features. However, it could generate the error in the step for fitting the statistical model.
- removeProtein_with1Feature : TRUE will remove the proteins which have only 1 peptide and charge. FALSE is default.

For further details, visit the help file using the following code.

```
## check options for converting format
?OpenSWATHtoMSstatsFormat
```

Now, we use OpenSWATHtoMSstatsFormat function for this example dataset. We chose to remove the proteins with only 1 feature.

** Features with great than 0.01 in m_score are removed.

```
## ** 0 features have all NAs or zero intensity values and are removed.
## ** All peptides are unique peptides in proteins.
## ** 31 features have 1 or 2 intensities across runs and are removed.
## ** All proteins have at least two features.
```

** No multiple measurements in a feature and a run.

This function shows the progress. The output of OpenMStoMSstatsFormat, called quant, is ready for next step.

```
## now 'quant' is ready for MSstats
head(quant)
```

```

5.4.3 Different options for OpenSWATH output of DIA experiment in dataProcess

In dataProcess, users need to use censoredInt='0' for OpenSWATH output.

Further steps is the same as in general workflow (section 4.1).

6. SRM analysis with MSstats

6.1 Suggested workflow for SRM

This section describes a typical workflow for SRM experiments with heavy labeled-isotope peptides. The example dataset, SRMRawData in MSstats is used for demonstration.

6.1.1 Preparing the data for MSstats input

The first step in using the MSstats is to format the data as described in Section 2. SRMRawData is already formatted for MSstats input.

```
# Check the first 6 rows in SRMRawData head(SRMRawData)
```

##		${\tt ProteinName}$	Pepti	deSequence	PrecursorCha	arge	${\tt FragmentIon}$	ProductCharge
##	243	IDHC	ATD	VIVPEEGELR		2	у7	NA
##	244	IDHC	ATD	VIVPEEGELR		2	у7	NA
##	245	IDHC	ATD	VIVPEEGELR		2	у8	NA
##	246	IDHC	ATD	VIVPEEGELR		2	у8	NA
##	247	IDHC	ATD	VIVPEEGELR		2	у9	NA
##	248	IDHC	ATD	VIVPEEGELR		2	у9	NA
##		<pre>IsotopeLabel</pre>	LType	Condition 1	BioReplicate	Run	Intensity	
##	243		Н	1	ReplA	1	84361.08350	
##	244		L	1	ReplA	1	215.13526	
##	245		Н	1	ReplA	1	29778.10188	
##	246		L	1	ReplA	1	98.02134	
##	247		H	1	ReplA	1	17921.29255	
##	248		L	1	ReplA	1	60.47029	

6.1.2 Processing the data

It is the same workflow as described in section 4.1.2. Only difference is the normalization with heavy labeled isotope peptides.

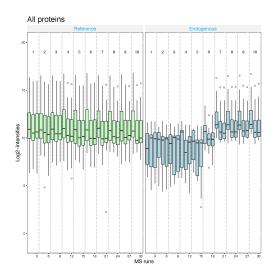

Different normalization option Let's see the different normalization effect with SRM dataset including two proteins.

```
unique(SRMRawData$ProteinName)
```

```
## [1] IDHC PMG2
## 45 Levels: ACEA ACH1 ACON ADH1 ADH2 ADH4 ALDH6 ALF CISY1 CISY2 DHSA ... SUCB
```

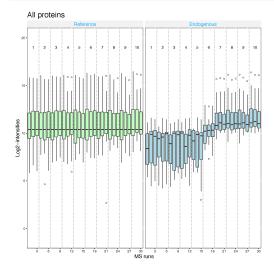

No normalization No normalization is performed. If you had your own normalization before MSstats, you should use like below.

```
srm.nonorm <- dataProcess(SRMRawData, normalization=FALSE)
dataProcessPlots(srm.nonorm, type='QCplot', address='srm_noNorm_')</pre>
```

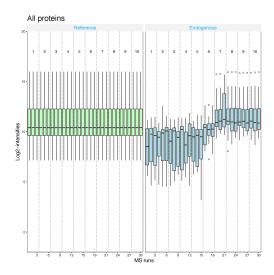

Equalize medians normalization The default option for normalization is 'equalizeMedians', where all the intensities in a run are shifted by a constant, to equalize the median of intensities across runs for label-free experiment. This normalization method is appropriate when we can assume that the majority of proteins do not change across runs. Be cautious when using the equalizeMedians option for a label-free dataset with only a small number of proteins. For label based experiment, equalizeMedians equalizes the median of reference intensities across runs and is generally proper even for a dataset with a small number of proteins.

```
srm.equalmed <- dataProcess(SRMRawData, normalization = 'equalizeMedians')
dataProcessPlots(srm.equalmed, type='QCplot', address='srm_equalM_')</pre>
```

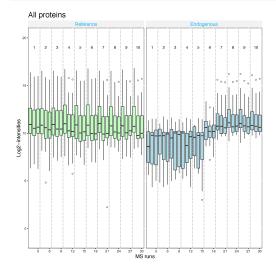

Quantile normalization The distribution of all the intensities in each run will become the same across runs for label-free experiment. For label-based experiment, the distribution of all the reference intensities will be become the same across runs and all the endogenous intensities are shifted by a constant corresponding to reference intensities.

```
srm.quantile <- dataProcess(SRMRawData, normalization='quantile')
dataProcessPlots(srm.quantile, type='QCplot', address='srm_quantile_')</pre>
```

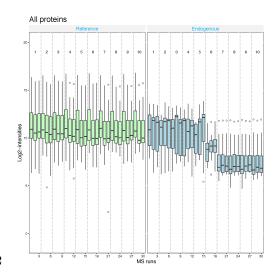

Global standards normalization: example 1 If you have a spiked in standard across all MS runs, you may set this to globalStandards and define the standard with nameStandards option. Global standard peptide or Protein names, which you can assume that they have the same abundance across MS runs, should be assigned in the vector for this option.

First, let's assume that PMG2 proteins is the spike-in protein and shoule be equal amount across MS runs.

Second, let's assume that IDHC proteins is the spike-in protein and shoule be equal amount across MS runs.

Global standards normalization: example 2

Further steps is the same as in general workflow (section 4.1).
